Optimal Left and Right Additive Schwarz Preconditioning for Minimal Residual Methods with Euclidean and Energy Norms

Marcus Sarkis\textsuperscript{1}, Daniel B. Szyld\textsuperscript{2}

Abstract

For the solution of non-symmetric or indefinite linear systems arising from discretizations of elliptic problems, two-level additive Schwarz preconditioners are known to be optimal in the sense that convergence bounds for the preconditioned problem are independent of the mesh and the number of subdomains. These bounds are based on some kind of energy norm. However, in practice, iterative methods which minimize the Euclidean norm of the residual are used, despite the fact that the usual bounds are non-optimal, i.e., the quantities appearing in the bounds may depend on the mesh size; see [X.-C. Cai and J. Zou, Numer. Linear Algebra Appl., 9:379–397, 2002]. In this paper, iterative methods are presented which minimize the same energy norm in which the optimal Schwarz bounds are derived, thus maintaining the Schwarz optimality. As a consequence, bounds for the Euclidean norm minimization are also derived, thus providing a theoretical justification for the practical use of Euclidean norm minimization methods preconditioned with additive Schwarz. Both left and right preconditioners are considered, and relations between them are derived. Numerical experiments illustrate the theoretical developments.

Key words: Additive Schwarz preconditioning. Krylov subspace iterative methods. Minimal residuals. GMRES. Indefinite and non-symmetric elliptic problems. Energy norm minimization.

1 Introduction

We consider minimal residual methods for the solution of non-symmetric or indefinite large systems of linear equations of the form

$$Bx = f,$$  \hspace{1cm} (1)

where $B$ is the discretization of a partial differential operator; see Section 2 for a description of the class of operators we consider. GMRES [26] is a popular Krylov subspace method for the iterative solution of non-symmetric linear systems, where at each step the norm of the residual is minimized over nested affine spaces of increasing dimension. The norm used in this minimization is usually taken to be the $l_2$ norm, i.e., the Euclidean norm associated with the standard inner product $(x, y) = x^T y$. For references on discussions of other inner products in this context, see Section 4.

Additive Schwarz (AS) refers to a class of extensively used preconditioners for (1); we describe them in Section 2. There are two main components to their appeal. First, they are easily parallelizable, since several smaller linear systems need to be solved: one system for each of the subdomains, usually corresponding to the restriction of the differential operator to that subdomain. These are called local problems. Second, if a coarse problem is introduced, they are optimal in the sense that bounds on the convergence rate of the preconditioned iterative method are independent (or slowly dependent) on the finite element mesh size and the number of subproblems; see, e.g., [24], [30], [32]. These bounds are given using some kind of energy norm (or equivalent Sobolev $H^1$ norm), i.e., the norm induced by the $A$-inner product $(x, y)_A = x^T A y$, for some appropriate symmetric positive definite matrix $A$. Usually $A$ is taken to be the symmetric part of $B$, i.e., $(B + B^T)/2$, if it is positive definite (i.e., if $B$ is positive real), or some other symmetric positive definite matrix related to $B$; see further Section 2 for the operators we consider here.

Cai and Zou [13] pointed out that when using AS with GMRES minimizing the $l_2$ norm of the residual, the optimality results of AS may be lost. They show explicit examples in which the quantities used in the GMRES convergence bounds depend on the mesh size. Nevertheless, this AS/GMRES method is widely used, e.g., it is standard in PETSc [4]; see also [24], [32]. In this paper, we present a version of GMRES where the minimization is done using some energy norm. In this form, we preserve the optimality of the preconditioner. Thus, both the bounds for the minimal residual method and those providing the independence of the mesh are in the same energy norm. By using the same energy norm in the minimization as that used to obtained the optimal bounds, one avoids the possible pitfalls of the mesh dependence in the bounds highlighted by Cai and Zou [13]. In particular we mention that while Cai and
Zou [13] found that certain operators cease to be positive real (in the $l_2$ norm), we show that they become positive real in the energy norm; cf. the discussion in [20, p. 32].

The iterative methods using the energy norm are more expensive at each step, and thus we do not advocate their use in practice in all cases; see Remark 7.1 for cases when it might be computationally advantageous to use the energy norm minimization methods. As it turns out, the analysis of the energy norm based methods do provide the theoretical justification for the use of the Euclidean norm based methods; see Section 6. We show that asymptotically, for a fixed mesh, the two behave in the same manner. Therefore, we say that the standard AS/GMRES is asymptotically optimal. We show experimentally that for many problems the asymptotic regime occurs rather rapidly, and thus, the number of iterations to achieve a desired small tolerance is the same using either method; see Section 7.

We consider both left and right preconditioning. We show relations between these two situations, both in the Euclidean and the energy norm; see Remark 3.1 and Proposition 5.1. These relations provide us with optimality results in both left and right preconditioning.

## 2 Additive Schwarz methods for a class of non-symmetric problems

In this section, we follow the description of a class of non-symmetric problems from [32, chapter 11]; see also [11], [12], [24], [30, section 5.4].

Let $\Omega \subset \mathbb{R}^d$ be a region of interest which is polygonal and an open bounded domain, and let $\mathcal{T}_h(\Omega)$ be a regular shaped and quasi-uniform triangulation of $\Omega$. Let $V$ be the traditional finite element space formed by piecewise linear and continuous functions vanishing on the boundary of $\Omega$; for details about finite elements formulations, see, e.g., [7], [8]. Consider the following discrete partial differential equation. Find $u \in V$ such that

$$b(u, v) = f(v) \quad \text{for all} \quad v \in V,$$

where

$$b(u, v) = a(u, v) + s(u, v) + c(u, v),$$

$$a(u, v) = \int_{\Omega} \nabla u \cdot \nabla v \, dx,$$

$$s(u, v) = \int_{\Omega} (b \cdot \nabla u)v + (\nabla \cdot bu)v \, dx, \quad b \in \mathbb{R}^d,$$

$$c(u, v) = \int_{\Omega} cuv \, dx, \quad \text{and} \quad f(v) = \int_{\Omega} fv \, dx.$$
We note that $a(\cdot, \cdot)$ is positive definite, $s(\cdot, \cdot)$ is antisymmetric, and $c(\cdot, \cdot)$ is an $L_2$ inner product with a weight function $c \in L^\infty$ smooth enough. Hence, if the mesh size is small enough, this problem has a unique solution [32].

Let $A$ and $B$ be the matrix representations of $v^T A u = a(u, v)$ and $v^T B u = b(u, v)$, respectively. We mention that these matrix representations depend on the type of boundary conditions, but not on the values of the boundary conditions. Since there is a one-to-one correspondence between functions in the finite element space and nodal values, sometimes we abuse the notation and do not distinguish between them. Let $\|v\|_a = (a(v, v))^{1/2}$, and $\|v\|_A = (v^T Av)^{1/2}$ be the corresponding norms in $V$ and in $\mathbb{R}^n$, respectively.

Considering zero Dirichlet boundary conditions and using elementary results we have:

(1) Continuity: there is a constant $C$, such that
$$|b(u, v)| \leq C\|u\|_a\|v\|_a, \quad u, v \in H^1_0(\Omega).$$

(2) A Gårding inequality: there is a constant $C$, such that
$$\|u\|^2_a - C\|u\|^2_{L^2(\Omega)} \leq b(u, u), \quad u \in H^1_0(\Omega).$$

(3) There is a constant $C$, such that
$$|s(u, v)| \leq C\|u\|_a\|v\|_{L^2(\Omega)}, \quad u, v \in H^1_0(\Omega),$$

and
$$|c(u, v)| \leq C\|u\|_{L^2(\Omega)}\|v\|_{L^2(\Omega)}, \quad u, v \in H^1_0(\Omega).$$

(4) Regularity (valid for polygonal and smooth domains): there is a constant $C$, independent of $g$, where the solution $w$ of the adjoint equation
$$b(\phi, w) = (g, \phi), \quad \phi \in H^1_0(\Omega),$$
satisfies
$$\|w\|_{H^{1+\gamma}(\Omega)} \leq C\|g\|_{L^2(\Omega)},$$
for some $\gamma > 1/2$.

We introduce a decomposition of $V$ into a sum of $N + 1$ subspaces $R^T_i V_i \subset V$, and
$$V = R^T_0 V_0 + R^T_1 V_1 + \cdots + R^T_N V_N.$$  \hfill (4)

Here we denote by $R^T_i : V_i \to V$ the extension operator from $V_i$ to $V$. We note that the decomposition (4) is not necessarily a direct sum of subspaces. Often, the subspaces $R^T_i V_i$, $i = 1, \ldots, N$, are related to a decomposition of the domain $\Omega$ into overlapping subregions $\Omega^i$ of size $O(H)$ covering $\Omega$. Here $\delta$ refers to the amount of overlap between the subregions. The subspace $R^T_0 V_0$
is the coarse space. For $u_i, v_i \in V_i$ define
\[ b_i(u_i, v_i) = b(R_i^T u_i, R_i^T v_i), \quad a_i(u_i, v_i) = a(R_i^T u_i, R_i^T v_i). \]

Let
\[ B_i = R_i B R_i^T, \quad A_i = R_i A R_i^T \]
be the matrix representations of these local bilinear forms. For $i = 0, \ldots, N$, we define $\tilde{P}_i : V \to V_i$, by
\[ b_i(\tilde{P}_i u, v_i) = b(u, R_i^T v_i), \quad v_i \in V_i, \]
and $\tilde{Q}_i : V \to V_i$ by
\[ a_i(\tilde{Q}_i u, v_i) = a(u, R_i^T v_i), \quad v_i \in V_i. \]

It is possible to show that the matrices $\tilde{Q}_i$ are well-defined (since the matrices $A_i$ are invertible) and for $H$ small enough the matrices $\tilde{P}_i$ are well-defined (since the matrices $B_i$ are invertible for small $H$); see [12], [32]. We now set
\[ P_i = R_i^T \tilde{P}_i = R_i^T B_i^{-1} R_i B, \quad Q_i = R_i^T \tilde{Q}_i = R_i^T A_i^{-1} R_i B, \]
and we introduce the additive operators

\[ P^{(1)} = \sum_{i=0}^{N} P_i = \left( \sum_{i=0}^{N} R_i^T B_i^{-1} R_i \right) B, \]
\[ P^{(2)} = P_0 + \sum_{i=1}^{N} Q_i = \left( R_0^T B_0^{-1} R_0 + \sum_{i=1}^{N} R_i^T A_i^{-1} R_i \right) B. \]

The following result can be found, e.g., in [12], [32].

**Theorem 2.1** There exist constants $H_0 > 0$, $c(H_0) > 0$, $C(H_0) > 0$, and $C_0(\delta)$, such that if $H \leq H_0$, then for $i = 1, 2$, and $u \in V$,
\[ \frac{a(u, P^{(i)} u)}{a(u, u)} \geq c_p, \]
and
\[ \| P^{(i)} u \|_a \leq C_p \| u \|_a, \]
where $C_p = C(H_0)$ and $c_p = C_0(\delta)^{-2} c(H_0)$.

We mention that similar bounds also hold for hybrid versions of the preconditioners [32].
3 Preconditioned GMRES

In this section we first review the standard preconditioned GMRES [26] (minimizing the Euclidean norm of the residual), which we use later as a model for other versions. We begin with left preconditioned GMRES.

It follows from the form of the preconditioners (5) and (6) that we can write generically

\[ P^{(i)} = M^{-1}B. \]

The first factor is indeed non-singular, so this notation is consistent; see [6], [18], [23]. The left preconditioned problem is therefore given by

\[ M^{-1}Bx = M^{-1}f. \]

Let \( x_0 \) be an initial approximation, \( r_0 = f - Bx_0 \) the corresponding initial residual, and \( s_0 = M^{-1}r_0 \). The left preconditioned GMRES minimizes the residual norm

\[ \|M^{-1}f - M^{-1}Bx\|_2 = \|M^{-1}r_0 - M^{-1}B(x - x_0)\|_2, \]

among all vectors \( x \) from the affine subspace

\[ x_0 + K^L_m = x_0 + \text{span}\{s_0, M^{-1}Bs_0, \ldots, (M^{-1}B)^{m-1}s_0\}, \]

where \( K^L_m \) is the Krylov subspace generated by \( M^{-1}B \) and \( s_0 \).

Let \( Z_m = [z_1, \ldots, z_m] \) be a matrix whose columns are an orthonormal basis of \( K^L_m \), such that the Arnoldi relation

\[ M^{-1}BZ_m = Z_{m+1}\tilde{H}^L_m \]

holds, where \( \tilde{H}^L_m \) is \((m + 1) \times m\) upper Hessenberg and \( z_1 = s_0/\beta \). Let \( \tilde{H}_m = \tilde{H}^L_m \). It follows that since we are looking for \( x - x_0 = Z_my \) for some \( y \in \mathbb{R}^m \), minimizing (10) is equivalent to finding the minimizer of the smaller problem

\[ y_m = \text{argmin}_{y \in \mathbb{R}^m} \|\beta e_1 - \tilde{H}_my\|_2, \]

and setting \( x_m = x_0 + Z_my_m \); see, e.g., [5], [25], for further algorithmic details.

We present next an algorithm to compute the \( m \)-th approximation \( x_m \) with left preconditioned GMRES. This algorithm correspond to full GMRES; for restarted GMRES one sets \( x_0 := x_m \) and restarts the iteration.

\textbf{Algorithm 3.1}

1. Compute \( r_0 = f - Bx_0, s_0 = M^{-1}r_0, \beta = (s_0, s_0)^{1/2}, \) and \( z_1 = s_0/\beta \)
2. For \( j = 1, \ldots, m \), Do:
3. Compute \( w := Bz_j \), and \( z := M^{-1}w \)
4. For \( i = 1, \ldots, j \), Do:
5. \( h_{i,j} := (z, z_i) \)
6. \( z := z - h_{i,j} z_i \)
7. EndDo
8. Compute \( h_{j+1,j} = (z, z)^{1/2} \) and \( z_{j+1} = z/h_{j+1,j} \)
9. EndDo
10. Define \( Z_m := [z_1, \ldots, z_m], \bar{H}_m = \{h_{i,j}\}_{1 \leq i \leq j+1; 1 \leq j \leq m} \)
11. Compute \( y_m = \arg\min_y \|\beta e_1 - \bar{H}_m y\|_2, \) and \( x_m = x_0 + Z_m y_m \)

Observe that the main storage requirements of Algorithm 3.1 are the vectors \( z_1, \ldots, z_m \in \mathbb{R}^n \).

Consider now the right preconditioned problem given by

\[
BM^{-1}u = f, \tag{13}
\]

where \( x = M^{-1}u \). Let \( u_0 = M x_0 \). The right preconditioned GMRES minimizes the residual norm \( \|f - BM^{-1}u\|_2 \), among all vectors \( u \) from the affine subspace

\[ u_0 + \mathcal{K}_m^R = u_0 + \text{span}\{r_0, BM^{-1}r_0, \ldots, (BM^{-1})^{m-1}r_0\}. \]

That is, \( u_m = u_0 + V_m y_m \), where here \( V_m \) is a matrix whose columns are an orthonormal basis of \( \mathcal{K}_m^R \). The Arnoldi relation in this case is

\[
BM^{-1}V_m = V_{m+1} \bar{H}_m^R. \tag{14}
\]

Thus \( x_m = M^{-1}u_m = x_0 + M^{-1}V_m y_m \), so that \( x_m \) can be computed directly from \( y_m \), and in fact

\[
x_m \in x_0 + M^{-1}\mathcal{K}_m^R, \tag{15}
\]

A standard algorithm for right preconditioned GMRES would be similar to Algorithm 3.1, with the appropriate changes, with one set of \( m \) vectors in \( \mathbb{R}^n \) as main storage requirement.

**Remark 3.1** We point out that there is a close relationship between left and right preconditioned GMRES; see, e.g., [25, Section 9.3.4]. In fact, it can be seen that \( M^{-1}\mathcal{K}_m^R = \mathcal{K}_m^L \) (cf. (15)), and therefore the columns of both \( Z_m \) and \( M^{-1}V_m \) are bases of the same space \( \mathcal{K}_m^L \). Since the columns of \( Z_{m+1} \) are orthogonal, there exists a non-singular upper triangular matrix

\[
U_{m+1} = \begin{bmatrix} U_m & u_{m+1} \\ 0^T & u_{m+1} \end{bmatrix}
\]

such that

\[
M^{-1}V_{m+1} = Z_{m+1} U_{m+1} = [Z_m \ z_{m+1}] U_{m+1}. \tag{16}
\]
Thus from (14), premultiplying by $M^{-1}$, and using (16) we obtain $M^{-1} B Z_m U_m = Z_{m+1} U_{m+1} \tilde{H}_m^R$. Comparing this with the Arnoldi relation for left preconditioning (11), we conclude that

$$\tilde{H}_m^L = U_{m+1} H_m^R U_{m}^{-1},$$

cf. [17] where a similar relation is found in a different context.

4 Convergence bounds for minimal residual methods

GMRES is in fact an implementation of the generalized conjugate residual method (GCR) [15] where the same minimization

$$\|r_m\|_2 = \min_{x \in x_0 + K_m} \| f - Bx \|_2,$$  (17)

is sought, where

$$K_m = K_m(B, r_0) = \text{span}\{r_0, Br_0, B^2r_0, \ldots, B^{m-1}r_0\}.$$  

The difference is that while in GMRES, as we have seen, the basis used for $K_m$ has orthogonal vectors, in GCR one constructs a basis of $K_m$ which is $B^TB$-orthogonal. There are also implementation differences. For example, as we have seen, in GMRES, the minimization problem is transformed into one of reduced size. This is performed with the QR factorization of $H_m$, where the orthogonal matrix $Q$ is not explicitly computed.

Thus, convergence analysis of GCR and GMRES is the same assuming exact arithmetic. We only mention GCR here to apply the convergence bounds developed for it to GMRES. There are two classical convergence bounds for these methods given in [16], [15, Theorem 3.3]. We present these bounds assuming the linear system (1) with no preconditioning, i.e., $M = I$. The first of these bounds assumes that $(B + B^T)/2$, the symmetric part of $B$, is positive definite, i.e., that $B$ is positive real. In this case, one has that

$$\|r_m\|_2 \leq \left(1 - \frac{c^2}{C^2}\right)^{m/2} \|r_0\|_2,$$  (18)

where for each real vector $x$,

$$c = \min_{x \neq 0} \frac{(x, Bx)}{(x, x)} \quad \text{and} \quad C = \max_{x \neq 0} \frac{Bx}{\|x\|_2}.$$  (19)

The bound (18) has been mentioned in conjunction with Schwarz preconditioners; see, e.g., [24], [32], [36], although Cai and Zou [13] present an example
where the operator is not positive real (in the $l_2$ norm), and therefore, this bound is not applicable.

Our aim is to consider a different norm in the minimization (17). Several authors explored the theory of such a different norm, either explicitly or implicitly, and mostly in a formal manner for the classification of Krylov subspace methods; see [2], [3, Chapter 12] [14], [21], [22], [33], [34], [35], and also [17] for a weighted norm, and [1] for a recent use of these ideas in a different context.

While the bound (18) and the constants (19) where originally derived using the Euclidean inner product and the associated norm, they are valid for minimal residual methods using any inner product and its induced norm; see, e.g., [14, Section 6.1], [20], [31], [24, Section 4.2], [36]. In other words, as long as $c > 0$ and $C$ is bounded, as defined in (19) with the proper inner product and norm, then, the bound (18) applies to a minimal residual method where the minimization is taken in the same norm. In the next section we provide an appropriate inner product and corresponding energy norm for the left and right preconditioned generalized minimal residual method.

5 Preconditioned GMRES minimizing some energy norm

In this section, we derive GMRES versions minimizing the energy norm of the residual. We discuss first the left preconditioned problem (9) minimizing the $A$-norm of the residual, where $A$ is a symmetric positive definite matrix. The right preconditioned problem is treated later in the section.

In terms of implementation of left preconditioned GMRES with the $A$-inner product, it suffices to replace appropriately each inner product in Algorithm 3.1, i.e., in steps 1, 5, and 8. For example, in step 5, we would have

$$h_{i,j} := (z, z_i)_A = z^T A z_i. \quad (20)$$

In this manner, the vectors $z_1, \ldots, z_m$ are $A$-orthonormal, i.e.,

$$Z_m^T A Z_m = I. \quad (21)$$

Note that this is different than the situation in [1] where an orthogonal basis (with respect to the Euclidean inner product) is kept. We point out that the usual Arnoldi relation (11) still holds here, but the basis matrix $Z_m$ and the upper Hessenberg matrix $\hat{H}_m = \hat{H}_m^L$ here are different than in (11).

If $x - x_0 = Z_m y$, $y \in \mathbb{R}^m$, i.e., writing $x \in x_0 + \mathcal{K}(M^{-1}B, M^{-1}r_0)$ using the $A$-orthonormal basis, because of (21), we have that
\[ \| M^{-1} f - M^{-1} B x \|_A = \| M^{-1} r_0 - M^{-1} B Z_m y \|_A = (22) \]

\[ \| Z_{m+1} \beta e_1 - Z_{m+1} \bar{H}_m y \|_A = \| \beta e_1 - \bar{H}_m y \|_2 , \tag{23} \]

and this is why we maintain the minimization in step 11 of Algorithm 3.1 in the \( l_2 \) norm also here. In summary, by replacing the inner products, we have a GMRES version minimizing the companion norm, i.e., the \( A \)-norm, but the smaller minimization problem (12) is still performed in the \( l_2 \) norm, in the same usual manner, e.g., using the QR factorization of \( \bar{H}_m \). Let us denote by \( y^A_m \) the minimizer in (23), \( x^A_m = x_0 + Z_m y^A_m \), and \( r^A_m = f - B x^A_m \), so we can distinguish the iterates and residuals of the method which minimizes the energy norm.

We observe that this algorithm, i.e., preconditioned GMRES minimizing the \( A \)-norm, can be implemented with only one matrix-vector product with \( A \) and one solution of the form \( M z = v \) per iteration, and by storing a set of additional vectors \( \tilde{z}_i = A z_i \).

The preceding discussion holds for any symmetric positive definite matrix \( A \). In the particular case where \( A \) is the discretization of (3), and \( B \) is the discretization of (2), we can use the results of Section 2 to obtain bounds on the operators used here. Specifically, Theorem 2.1 implies that there exist constants \( C_p \) and \( c_p \) such that for all real vectors \( x \),

\[ \frac{(x, M^{-1} B x)_A}{(x, x)_A} \geq c_p \quad \text{and} \quad \| M^{-1} B x \|_A \leq C_p \| x \|_A . \tag{24} \]

These bounds are the counterparts to (7) and (8). The bound (18) is valid for the \( A \)-norm, and the minimization in (22) is also in the same \( A \)-norm. Thus, the combination of AS with this version of GMRES has the following convergence bound independent of the finite element mesh size and the number of local problems

\[ \| M^{-1} r^A_m \|_A \leq \left( 1 - \frac{c_p^2}{C_p^2} \right)^{m/2} \| M^{-1} r_0 \|_A . \tag{25} \]

We remark that this convergence bound points to the interplay between the choice of the energy norm used in the minimal residual method, i.e., the symmetric positive definite matrix \( A \), and the choice of preconditioner \( M^{-1} \). The idea is that the matrix \( M^{-1} B \) must be positive real in the \( A \)-inner product, i.e., \( c_p > 0 \). In general, \( A \) should be chosen as the elliptic highest order term derivative of \( B \). By selecting a coarse mesh and local problems sufficiently small, local Poincaré inequalities force the positiveness of \( M^{-1} B \) in the \( A \)-norm. Note that from (24), \( c_p/C_p \leq 1 \). The closer the ratio \( c_p/C_p \) is to 1, the smaller is the factor in parenthesis in the convergence bound (25).

Consider now the right preconditioned system (13) where, as before, \( x = \)](10)
Simple calculations give

\[(x, x)_{\mathcal{A}} = (u, u)_{{M^{-T}A^{-1}M^{-1}}} , \quad (x, M^{-1}Bx)_{\mathcal{A}} = (u, BM^{-1}u)_{M^{-T}A^{-1}} , \quad (M^{-1}Bx, M^{-1}Bx)_{\mathcal{A}} = (BM^{-1}u, BM^{-1}u)_{M^{-T}A^{-1}} .\]  

(26)

and

\[(M^{-1}Bx, M^{-1}Bx)_{\mathcal{A}} = (BM^{-1}u, BM^{-1}u)_{M^{-T}A^{-1}} .\]  

(27)

Let \(G = M^{-T}A^{-1}M^{-1}\). It follows then, that we can rewrite the bounds (24) as

\[
\frac{(u, BM^{-1}u)_{G}}{(u, u)_{G}} \geq c_p, \quad \text{and} \quad \|BM^{-1}u\|_{G} \leq C_p \|u\|_{G}
\]

with the same constants \(c_p\) and \(C_p\). Consequently, \(M\) is an optimal right preconditioner for a minimal residual method using the energy norm associated with the symmetric positive definite matrix \(G = M^{-T}A^{-1}\), i.e., minimizing

\[
\|r_0 - BM^{-1}u\|_{M^{-T}A^{-1}} .
\]  

(28)

A right preconditioned GMRES such that it minimizes (28) can be implemented from the standard right preconditioned GMRES by using instead the \(M^{-T}A^{-1}\)-inner product. For example, in the construction of the upper Hessenberg matrix one would have

\[
h_{i,j} := (w, v_i)_{M^{-T}A^{-1}} = (M^{-1}w)^{T}A^{-1}v_i .
\]  

(29)

In this manner, the vectors \(v_1, \ldots, v_m\) are \(M^{-T}A^{-1}\)-orthonormal, and in a manner similar to the left preconditioning case, we have that

\[
\|r_0 - BM^{-1}u\|_{M^{-T}A^{-1}} = \|r_0 - BM^{-1}V_m y\|_{M^{-T}A^{-1}}
\]

\[
\|V_{m+1}(\beta e_1 - \bar{H}_m y)\|_{M^{-T}A^{-1}} = \|\beta e_1 - \bar{H}_m y\|_2 .
\]  

(30)

Therefore, in the implementation of the right preconditioned GMRES which minimizes the \(M^{-T}A^{-1}\)-norm, the smaller least squares problem remains in the \(l_2\) norm. Let us denote by \(y^G_m\) the minimizer in (30), \(x^G_m = x_0 + Z_m y^G_m\), and \(r^G_m = f - Bx^G_m\).

Let \(Z_m = M^{-1}V_m = [z_1, \ldots, z_m]\), then using identities (26)–(27), we can write

\[
\|r_0 - BM^{-1}V_m y\|_{M^{-T}A^{-1}} = \|M^{-1}r_0 - M^{-1}BM^{-1}V_m y\|_A = \|\beta z_1 - M^{-1}BZ_m y\|_A .
\]

In other words, for any fixed preconditioner \(M\), using right preconditioning and minimizing the \(M^{-T}A^{-1}\)-norm of the residual, produces (in exact arithmetic) the same approximations than if one uses left preconditioning and minimizes the \(A\)-norm of the appropriately transformed residual. Furthermore,
from (20) and (29) one can see that the upper Hessenberg matrices $\tilde{H}_m$ in (23) and (30) are the same matrix, cf. Remark 3.1. We summarize this in the following result.

**Proposition 5.1** For every preconditioner $M$ and every symmetric positive definite matrix $A$, the minimal residual method for the left preconditioned problem $M^{-1}Bx = M^{-1}b$ using the $A$-inner product is completely equivalent (in exact arithmetic) to a minimal residual method for the right preconditioned problem $BM^{-1}u = b$, $M^{-1}u = x$, using the $G$-inner product, with $G = M^{-T}AM^{-1}$. In particular this holds for $A = I$, i.e., for the Euclidean inner product. Conversely, if we have a right preconditioned problem $BM^{-1}u = b$, $M^{-1}u = x$, with the Euclidean inner product, it is completely equivalent to the left preconditioned problem $M^{-1}Bx = M^{-1}b$ using the $A$-inner product where $A = M^T M$, so that $M^{-T}AM^{-1} = I$.

We remark that here we have the same upper Hessenberg matrix $\tilde{H}_m$ for both left and right preconditioning, but with different norms, while in Remark 3.1 we have the same norm, but different upper Hessenberg matrices.

From Proposition 5.1 it follows that for the right preconditioned GMRES with $M^{-T}AM^{-1}$-norm, we have the same convergence bound (25), with the same constants, i.e.,

$$\|r^G_m\|_G \leq \left(1 - \frac{C_p^2}{C_p^2}\right)^{m/2} \|r_0\|_G.$$  \hspace{1cm} (31)

In terms of implementation, one can then use Algorithm 3.1 with the $A$-inner product. It goes without saying that while optimality of AS with GMRES is assured, there is the cost of one matrix-vector product with the symmetric positive definite matrix $A$ in each iteration.

### 6 Bounds for AS/GMRES in Euclidean norm

We begin this section by discussing the constants of equivalency between an energy norm and the Euclidean norm.

**Proposition 6.1** Let $H$ be a symmetric positive definite matrix, and the associated inner product $(x,y)_H = x^T H y$ and norm $\|x\|_H = (x,x)_H^{1/2}$. Then for any vector $x$ one has

$$\|x\|_2 \leq c_H \|x\|_H \quad \text{and} \quad \|x\|_H \leq C_H \|x\|_2,$$

where $c_H = 1/\sqrt{\lambda_{\text{min}}(H)}$, $C_H = \sqrt{\lambda_{\text{max}}(H)}$, and $\lambda_{\text{min}}(H)$, $\lambda_{\text{max}}(H)$ represent the minimum and maximum eigenvalues of $H$, respectively.
Proof. Let

\[ c_H^2 = \sup_{x \neq 0} \frac{\|x\|_H^2}{\|x\|_2^2} = \left( \inf_{x \neq 0} \frac{\|x\|_H^2}{\|x\|_2^2} \right)^{-1} = \left( \inf_{x \neq 0} \frac{x^T H x}{x^T x} \right)^{-1} = \frac{1}{\lambda_{\min}(H)}, \]

and the first inequality follows. The proof of the second inequality is analogous. □

We relate now the norm of the residual \( r_m^L \) of the usual left preconditioned GMRES method minimizing the Euclidean norm, i.e., obtained using Algorithm 3.1, with \( r_m^A \) obtained from the left preconditioned GMRES minimizing the energy norm defined by the symmetric positive definite matrix \( A \). We use the constants \( c_A = 1/\sqrt{\lambda_{\min}(A)} \), \( C_A = \sqrt{\lambda_{\max}(A)} \), and \( \kappa(A) = c_A^2 C_A^2 \), the condition number of \( A \). Then we have that

\[
\|M^{-1} r_m^L\|_2 \leq \|M^{-1} r_m^A\|_2 \leq c_A \|M^{-1} r_m^A\|_A \leq c_A \left( 1 - \frac{c_p^2}{C_p^2} \right)^{m/2} \|M^{-1} r_0\|_A
\]

(32)

\[
\leq c_A C_A \left( 1 - \frac{c_p^2}{C_p^2} \right)^{m/2} \|M^{-1} r_0\|_2
\]

\[
= \sqrt{\kappa(A)} \left( 1 - \frac{c_p^2}{C_p^2} \right)^{m/2} \|M^{-1} r_0\|_2 ,
\]

where the first inequality follows from the fact that \( r_m \) is the minimizing residual (in the Euclidean norm), the second from Proposition 6.1, the third from (18), and the constants \( c_p \) and \( C_p \) come from (24).

In a similar fashion, we obtain bounds for the residual norm of \( r_m^R \) obtained using right preconditioned AS/GMRES minimizing the Euclidean norm and relate these to those of \( r_m^G \) obtained using right preconditioned AS/GMRES minimizing the \( G \)-norm. Using the same arguments, and (31), we have

\[
\|r_m^R\|_2 \leq \|r_m^G\|_2 \leq c_G \|r_m^G\|_G \leq c_G \left( 1 - \frac{c_p^2}{C_p^2} \right)^{m/2} \|r_0\|_G
\]

\[
\leq c_G C_G \left( 1 - \frac{c_p^2}{C_p^2} \right)^{m/2} \|r_0\|_2 = \sqrt{\kappa(G)} \left( 1 - \frac{c_p^2}{C_p^2} \right)^{m/2} \|r_0\|_2 , \quad (33)
\]

where \( c_G = 1/\sqrt{\lambda_{\min}(G)} \), \( C_G = \sqrt{\lambda_{\max}(G)} \), and \( \kappa(G) = c_G^2 C_G^2 \) is the condition number of \( G \).

Several observations regarding the bounds (32)–(33) are in order. These bounds show that the (left and right preconditioned) AS/GMRES (using Euclidean
norm minimization) is asymptotically optimal, in the sense that other than the factor $\sqrt{\kappa(A)}$ or $\sqrt{\kappa(G)}$ (which do depend on the mesh size) the convergence is independent of the mesh size or the number of subdomains. These fixed factors are eventually overtaken by the other factor being reduced with each iteration. The positive definite matrix $A$ defining the energy norm needs to be sufficiently far from being singular, i.e., $\lambda_{\text{min}}(A)$ sufficiently far from zero, so that the asymptotic behavior takes hold. This is usually the case in practice, and it is illustrated with examples in the next section, where one has that $\lambda_{\text{min}}(A) = O(1)$, and $\kappa(A) = O(1/h^2)$. Note that the constants $c_p$ and $C_p$ depend on the existence of the positive definite matrix $A$ (or operator $a(u, v)$) for which (24) hold. In other words, we have derived the asymptotic optimality of AS/GMRES (using Euclidean norm minimization) through the optimality of the method using an energy norm.

We also see from the above bounds that the 2-norm of the usual GMRES residual differs from that of the energy norm GMRES residual by no more than a factor $c_A$ or $c_G$ (which is fixed for all $x_0$ and all $m$). Thus, asymptotically, as the residuals go to zero, their norms behave in the same manner. This fact is well illustrated in some examples in the next section.

7 Numerical Experiments

We present numerical experiments associated to partial differential equations of the form $-\Delta u + b \cdot \nabla u + ku = 1$, with zero Dirichlet boundary conditions on the two-dimensional unit square; these are particular cases of (2). The three cases we investigate are:

- A. The Helmholtz equation where we take $b^T = [0, 0]$, and two different values $k = -5$ and $k = -120$, the latter being indefinite.
- B. The implicit one-step time discretization of an advection-diffusion equation, where $b^T = [10, 20]$, $k = 1$, and upwind discretization is used.

We consider the following four mesh and domain decomposition configurations: Mesh $64 \times 64$ elements decomposed on $4 \times 4$ subdomains; Mesh $128 \times 128$ decomposed on $4 \times 4$ or $8 \times 8$ subdomains; and Mesh $256 \times 256$ decomposed on $8 \times 8$ subdomains. For each of these cases, we consider three different amounts of overlap $\delta = 0$, $\delta = 1$, or $\delta = 2$. An overlap of $\delta = 0$ indicates one layer of overlapping nodes, i.e., the interface nodes, while $\delta = 1$ or 2 correspond to three or five layers of overlapping nodes, respectively. The coarse space is based on partition of unity with one degree of variables per subdomains [9], [27], [28], [29]. We consider the additive preconditioner $P^{(1)}$ of (5). We show results using right preconditioning. In the figures we plot the either Euclidean norm or the $G$-norm the residual using the two strategies: using
the right GMRES with $G$-norm minimization (plotted with $(*)$) and using the standard right GMRES with Euclidean norm minimization (plotted with $(o)$). In all cases our tolerance for the relative residual norm is $\varepsilon = 10^{-8}$. Recall that the right GMRES with $G$-norm minimization is equivalent to the left GMRES with $A$-norm minimization; see Proposition 5.1.

![Fig. 1. Problem A. Helmholtz equation with $k = −5$. Relative residual norms for GMRES minimizing the $l_2$ norm (o), and the $G$-norm (*). $64 \times 64$ grid, $4 \times 4$ subdomains, $\delta = 0$. Left: Residuals measured in the $G$-norm. Right: Residuals measured in the $l_2$ norm.](image1)

![Fig. 2. Problem A. Helmholtz equation with $k = −120$. Relative residual norms for GMRES minimizing the $l_2$ norm (o), and the $G$-norm (*). $128 \times 128$ grid, $8 \times 8$ subdomains, $\delta = 1$. Left: Residuals measured in the $G$-norm. Right: Residuals measured in the $l_2$ norm.](image2)

We present in Figures 1–3 representative runs for the Helmholtz equation, and in Figures 4–6 representative runs for the advection-diffusion equation. In each figure, we show the same problem solved with the standard AS/GMRES minimizing the Euclidean norm, and with the method minimizing the $G$-norm. We present the same results in two different graphs, one, on the left measuring the two residuals $r^R_m$ and $r^G_m$ in the $G$-norm, and the second, on the right, measuring them in the Euclidean norm. It can be appreciated from these figures that, as expected, $\|r^G_m\|_G \leq \|r^R_m\|_G$ (left plots), and that $\|r^R_m\|_2 \leq \|r^G_m\|_2$ (right plots). It can also been clearly seen how asymptotically the two sequences of residual norms are very close to each other, and that the asymptotic regime begins well before the method reaches the desired tolerance.
Fig. 3. Problem A. Helmholtz equation with $k = -120$. Relative residual norms for GMRES minimizing the $l_2$ norm (o), and the $G$-norm (*). 256 × 256 grid, 8 × 8 subdomains, $\delta = 0$. Left: Residuals measured in the $G$-norm. Right: Residuals measured in the $l_2$ norm.

Fig. 4. Problem B. Advection-diffusion equation. Relative residual norms for GMRES minimizing the $l_2$ norm (o), and the $G$-norm (*). 64 × 64 grid, 4 × 4 subdomains, $\delta = 0$. Left: Residuals measured in the $G$-norm. Right: Residuals measured in the $l_2$ norm.

Remark 7.1 Depending on the problem, and especially if a low tolerance desired, it may turn out to be less expensive to reach the desired tolerance in the energy norm than in the $l_2$ norm. In addition, the energy norm may be more meaningful. We call the reader’s attention to Figure 6 where $\|M^{-1}r^A_m\|_A$ falls below $10^{-4}$ after 22 iterations, while it takes 40 iterations for $\|M^{-1}r^L_m\|_2$ to fall below the same tolerance. Thus, in this case the additional cost of one matrix-vector product with the SPD matrix $A$ per step is more than offset by the savings in number of iterations.

We report in Tables 1 and 2 results on runs with the usual AS/GMRES ($l_2$ norm minimization) with the two cases of the Helmholtz problem considered here, and in Table 3 with the advection-diffusion problem already mentioned. We show the number of iterations to reach a relative residual norm below $10^{-8}$ for all the meshes described, and three different levels of overlap. In the tables, $n$ stands for the number of points in one side of the mesh, and nsub, in parenthesis, the numbers of subdomains in each side of the square mesh.

Table 1
Problem A. Helmholtz equation with $k = -5$. Number of iterations for AS/GMRES convergence

As it can be appreciated in these tables, while the number of iterations is not constant across each row, i.e., for each preconditioner considered, they do not grow unbounded; indeed they only about double when the value of $h$ is reduced by a factor of four, i.e., when the cell size is reduced by a factor of sixteen.

8 Conclusion

We make the case, both theoretically and experimentally, that the two-level additive Schwarz preconditioning is asymptotically optimal when combined with a minimal residual iterative method such as GMRES. The key here is that the methods are optimal when the minimal residual iterative method uses the same energy norm as that used to derive the optimal Schwarz bounds, and the asymptotic optimality of the usual method (minimizing the Euclidean norm) is obtained as a consequence. We also developed an equivalence between left and right preconditioned methods.
